Introduction

How do species pools change over time as species are recruited or go extinct? When are ecotypes enriched or depleted? How does global and regional environmental context affect the distribution of species ecotypes (e.g. guilds) in a regional species pool?

A regional species pool is the set of species which form communities in a specific region; local communities are subsets of the regional pool. The composition of a regional species pool changes over time due to speciation, migration, extinction. Local scale processes like resource competition only affect the regional species pool if all communities are affected.

Valentine and Bambach how they presented guilds in paleobiology. Bush and Bambach presented an ecocube to describe what how marine invertebrates partition space and resources CITATION.

Unique combinations represent what possible ecotypes are observable. The distribution of ecocube occupancy is then normally analyzed using ordination methods and the change in disparity over is estimated CITATION.

Fourth-corner modeling is concerned with explaining either species abundance or presence/absence as a product of species traits, environmental factors, and the interaction between these factors. In modern ecological studies, the matrix being modeled is of species occurrence at localities distributed in region. In this study, the matrix being modeled is of species occurrence in temporal bins across the Cenozoic in North America. These dimensions are all axes of the same three dimensional occurrence matrix: species by locality by time.

One of the greatest challenges with analyzing species occurrence data is the inherent incompleteness of any sample CITATION. In the modern, only presences are certain as an absence can be caused by both the species being truly absent or the species never having been sampled CITATION. For paleontological data in the context of this study, the incomplete preservation of fossil communities combined with the incomplete sampling of what fossils there are means that the true times of origination or extinction may not be observed CITATION.

? found several systematic differences in mammal species durations associated with various species

traits. Omnivorous taxa were found to have, on average, a greater duration than other dietary
28 categories. Additionally, arboreal taxa were found to have a shorter duration than other locomotor
categories.

30 An unresolved question from ? is whether the greater extinction risk faced by arboreal is constant
over time or if there was a change in extinction risk at the Paleogene/Neogene boundary.

32 Specifically, the question is whether the extinction risk arboreal taxa increased in the Neogene,
driving the loss of arboreal taxa and average extinction risk of arboreal taxa down.

34 There are no observed massive taxonomic turnover events in the North American record, unlike the
Neogene record Europe CITATION ALROY OTHERS.

36 The effect of climate on diversity and the diversification process has been the focus of considerable
research with many analyses favoring diversification being more biologically-mediated than
38 climate-mediated CITATION. Scale of analysis makes a big difference in interpretation of results,
both temporal and geographic. For example when the mammal fossil record analyzed at small
40 temporal and geographic scales a correlation between diversity and climate are observable
CITATION CLYDE. However, when the record is analyzed at the scale of the continent and the
42 Cenozoic there is no correlation with diversity and climate CITATION ALROY. This results,
however, does not go against the idea that there may be short periods of correlation and that this
44 correlation change or reverse direction over time; instead this result means that there is no single
direction of correlation between diversity and climate.

46 There are many global climatic events that may have influenced the distribution of mammal
ecotypes regionally, if not globally CITATION. PETM. The Mid-Miocene climactic optimum. The
48 general cooling throughout the Cenozoic and the development of ice-caps in the Neogene. The
Oligo-Miocene boundary. The transition from the Paleogene to the Neogene in North America is
50 typically described as the “opening-up” of the landscape as partially forested environments were
replaced by savannah and grasslands CITATION.

Materials and Methods

Taxon occurrences and species-level information

All fossil occurrence information was downloaded from the Paleobiology Database. Occurrences (PBDB) were restricted to all Mammalia sampled in North America between the Maastrichtian and Gelasian stages. Taxonomic, stratigraphic, and ecological metadata for each occurrence was included. The raw data is available for download at <http://goo.gl/2slgeU>.

This raw data was then sorted, cleaned, and manipulated programmatically prior to analysis. Species taxonomic assignments given by the PBDB were updated for accuracy and consistency. For example, species classified in the order Artiodactyla were reclassified as Cetartiodactyla. These

re-assignments follow ? and were based on CITATIONS. Additionally, Taxa who’s life habit was
 62 classified as either volant (i.e. Chiroptera) or aquatic (e.g. Cetacea) were excluded from this
 analysis because of both differences in fossilization potential and applicability to the study of
 64 terrestrial species pools.

The life habit and dietary categories provided through the PBDB were coarsened to increase per
 66 ecotype sample size; this coarsening follows the same procedure as ?. Additionally, life habit
 category was further modified to break-up the vague “ground-dwelling” category; re-classifying
 68 these species by ankle posture gives more precise information about that species’ environmental
 context. Ground-dwelling taxa were reassigned following ? by species taxonomic context. Species
 70 ecotype is defined as the interaction between life habit and diet categories. Ecotype categories with
 less than 10 species havig ever been that combination were excluded, yielding a total of 18 of 21
 72 possible ecotypes.

Table 1: Species trait assignments in this study are a coarser version of the information available
 in the PBDB. Information was coarsened to improve per category sample size and uniformity and
 followed this table.

This study		PBDB categories
Diet	Carnivore	Carnivore
	Herbivore	Browser, folivore, granivore, grazer, herbivore.

Species mass information was gathered from multiple different sources where a plurality of the body size estimates are from the PBDB. Body part measurements for many species are also available through the PBDB. Just as with ?, these measurements and corresponding regression equations were used to get mass estimates for more species. Additional mass estimates and body part measurements were sourced from CITATIONS, the Neogene Old World Database as in ?. Mass was log-transformed and then mean-centered and rescaled by dividing by two-times its standard deviation; this insures that the magnitude of effects for both continuous and discrete covariates are comparable and follows CITATION.

All fossil occurrences from 64 to 2 million years ago (Mya) were binned into 31 2 million year (My) bins. This temporal length was chosen because it is approximately the resolution of the North American mammal fossil record.

Table 3: Regression equations used in this study for estimating body size. Equations are presented with reference to taxonomic grouping, part name, and reference.

Group	Equation	log(Measurement)	Source
General	$\log(m) = 1.827x + 1.81$	lower m1 area	?
General	$\log(m) = 2.9677x - 5.6712$	mandible length	?
General	$\log(m) = 3.68x - 3.83$	skull length	?
Carnivores	$\log(m) = 2.97x + 1.681$	lower m1 length	?
Insectivores	$\log(m) = 1.628x + 1.726$	lower m1 area	?
Insectivores	$\log(m) = 1.714x + 0.886$	upper M1 area	?
Lagomorph	$\log(m) = 2.671x - 2.671$	lower toothrow area	?
Lagomorph	$\log(m) = 4.468x - 3.002$	lower m1 length	?
Marsupials	$\log(m) = 3.284x + 1.83$	upper M1 length	?
Marsupials	$\log(m) = 1.733x + 1.571$	upper M1 area	?
Rodentia	$\log(m) = 1.767x + 2.172$	lower m1 area	?
Ungulates	$\log(m) = 1.516x + 3.757$	lower m1 area	?
Ungulates	$\log(m) = 3.076x + 2.366$	lower m2 length	?
Ungulates	$\log(m) = 1.518x + 2.792$	lower m2 area	?
Ungulates	$\log(m) = 3.113x - 1.374$	lower toothrow length	?

Environmental and temporal covariates

86 The group-level covariates in this study are descriptors of species' environmental context, such as global temperature and floral interval.

88 Global temperature was calculated from Mg/Ca isotope data across the Cenozoic CRAMER CITATION. WHY DID I DO THIS? TOM EZARD HAS USED THIS AND IT IS PROBABLY

90 BETTER THAN THE ZACHOS CURVE. Two aspects of the Mg/Ca-based temperature curve were included in this analysis: mean and range. Both were calculated as the mean of all respective

92 estimates for each 2 My temporal bins. Both mean and range were then rescaled as above: subtract mean, divide by twice the standard deviation.

94 Floral interval is a holistic descriptor of which taxonomic groups are present and their relative modernity of those taxa for a given temporal interval CITATION. Graham CITATION defines four

96 intervals from the Cretaceous to the Pliocene; only three of these intervals are included in this analysis.

98 Modelling species occurrence

Two different models were used in this study: a pure-presence model and a birth-death model. Both
100 models at their core are hidden Markov model with an absorbing state. The difference between
these two models is if the probability of a species origination and survival are considered equal or
102 different.

Data augmentation

104 All presence/absence observations are incomplete. The hidden Markov model at the core of this
analysis allows for observed absences to be used meaningfully to estimate the number of unobserved
106 species. Of specific concern in this analysis is the unknown “true” size of the dataset; how many
species could have actually been observed? While many species have been observed, the natural
108 incompleteness of all observations, especially in the case of paleontological data, there are obviously
many species which were never sampled.

110 Let N be the total number of observed species, M be the upper limit of possible species that could
have existed given a model of species presence, and N^* is the all-zero histories where $N^* = M - N$.
112 This approach assumes that $\hat{N} \sim \text{Binomial}(M, \psi)$ where \hat{N} is the estimated “true” number of
species and ψ is the probability that any augmented species should actually be “present.” Because
114 M is user defined, this approach effectively gives ψ a uniform prior over N to M CITATION. For a
more detailed explanation of data augmentation and its application here, please see CITATION,
116 CITATION, and CITATION. For this study, $M = N + \lfloor N/4 \rfloor$.

Data imputation is the process of estimating missing data for partially observed covariates
118 CITATION, this is simple in a Bayesian context because data are also parameters CITATION.
Augmented species also have no known mass so a mass estimate must be imputed for each possible
120 species CITATION ROYLE. This procedure assumes that mass values for augmented species are
from the same distribution as observed species. The distribution of observed mass values is
122 estimated as part of the model, and new mass values are then generated from this distribution.

Table 4: Observation parameters

Parameter	dimensions	explanation
y	$N \times T$	observed species presence/absence
z	$N \times T$	“true” species presence/absence
p	T	probability of observing a species that is present at time t
m	N	species log mass, rescaled
α_0	1	average log-odds of p
α_1	1	change in average log-odds of p per change mass
r	T	difference from α_0 associated with time t
σ	1	standard deviation of r

This approach is an example of imputing data missing completely at random CITATION. Because
124 log mass values are rescaled as a part of this study, the body mass distribution is already known
($\mathcal{N}(0, 0.5)$); augmented species body mass just simply drawn from this distribution.

126 In addition to body mass information, the augmented species need an ecotype classification. Because
these species are completely unknown, they were all classified as “augmented,” an additional
128 grouping indicating their unknown biology. This classification has no biological interpretation.

Observation process

130 The type of hidden Markov model used in this study has three characteristic probabilities:
probability p of observing a species given that it is present, probability ϕ of a species surviving from
132 one time to another, and probability π of a species first appearing CITATION. In this formulation,
the probability of a species going extinct is $1 - \pi$. For the pure-presence model $\phi = \pi$, while for the
134 birth-death model $\phi \neq \pi$.

The probability of observing a species that is present p is modeled as a logistic regression was a
136 time-varying intercept and species mass as a covariate. The effect of species mass on p was assumed
linear and constant over time and given a prior reflecting a possible positive relationship; these
138 assumptions are reflected in the structure of the model Equation 1. The parameters associated with
this part of the model are described in Table 4.

Table 5: Parameters for the model of presence in the pure-presence model

Parameter	dimensions	explanation
z	$N \times T$	“true” species presence/absence
θ	$N \times T - 1$	probability of $z = 1$
a	$T - 1 \times D$	ecotype-varying intercept; mean value of log-odds of θ
m	N	species log mass, rescaled
b_1	1	effect of species mass on log-odds of θ
b_2	1	effect of species mass, squared, on log-odds of θ
U	$T \times D$	matrix of group-level covariates
γ	$U \times D$	matrix of group-level regression coefficients
Σ	$D \times D$	covariance matrix of a
Ω	$D \times D$	correlation matrix of a
τ	D	vector of standard deviations for each ecotype a_d

$$y_{i,t} \sim \text{Bernoulli}(p_{i,t}z_{i,t})$$

$$p_{i,t} = \text{logit}^{-1}(\alpha_0 + \alpha_1 m_i + r_t) \quad (1)$$

$$r_t \sim \mathcal{N}(0, \sigma)$$

140 Pure-presence process

For the pure-presence model there is only a single probability dealing with the presence of a species
142 θ . This probability was modeled as multi-level logistic regression with both species-level and
group-level covariates CITATION. The parameters associated with pure-presence model are
144 presented in Table 5 and the full sampling statement in Equation 2.

The species-level of the model (Eq. 2) is a logistic regression with varying-intercept that varies by
146 ecotype. Additionally, species mass was included as a covariate associated with two regression
coefficients allowing a quadratic relationship with log-odds of occurrence. This assumption is based
148 on the known distribution of mammal body masses where species with intermediate mass values are
more common than either small or large bodied species. These assumptions are also reflected in the
150 choice of priors for these regression coefficients.

The values of each ecotype’s intercept are themselves modeled as regressions using the group-level
152 covariates associated with environmental context. Each of these regressions has an associated

variance of possible values of each ecotype's intercept CITATION. In addition, the covariances

154 between ecotype intercepts, given this group-level regression, are modeled CITATION.

Following recommendations from CITATION, CITATION, CITATION all parameters not modeled

156 elsewhere were given weakly informative priors. Weakly informative means that priors do not

necessarily encode actual prior information but instead help regularize or weakly constrain posterior

158 estimates. These priors have a concentrated probability density around and near zero; this has the

effect of tempering our estimates and help prevent overfitting the model to the data CITATION.

$$\begin{aligned}
y_{i,t} &\sim \text{Bernoulli}(p_{i,t}z_{i,t}) & \alpha_0 &\sim \mathcal{N}(0, 1) \\
p_{i,t} &= \text{logit}^{-1}(\alpha_0 + \alpha_1 m_i + r_t) & \alpha_1 &\sim \mathcal{N}(1, 1) \\
r_t &\sim \mathcal{N}(0, \sigma) & \sigma &\sim \mathcal{N}^+(1) \\
z_{i,t} &\sim \text{Bernoulli}(\theta_{i,t}) & b_1 &\sim \mathcal{N}(0, 1) \\

\Sigma &= \text{diag}(\tau)\Omega\text{diag}(\tau) & \tau &\sim \mathcal{N}^+(1) \\
& & \Omega &\sim \text{LKJ}(2)
\end{aligned} \tag{2}$$

160 Birth-death process

In the birth-death model, $\phi \neq \pi$ and so each of these probabilities are modeled separately but in a

162 similar manner to how θ is modeled in the pure-presence model (Eq. 2). The parameters associated

with the birth-death presence model are presented in Table 6 and the full sampling statement,

164 including observation (Eq. 1), is described in Equation 3.

Similar to the pure-presence model, both ϕ and π are modeled as logistic regressions with

166 varying-intercept and one covariate associated with two parameters. The possible relationships

between mass and both ϕ and π are reflected in the parameterization of the model and choice of

Table 6: Parameters for the model of presence in the pure-presence model

Parameter	dimensions	explanation
z	$N \times T$	“true” species presence/absence
ϕ	$N \times T - 1$	probability of $z_{-,t} = 1 z_{-,t-1} = 0$
π	$N \times T - 1$	probability of $z_{-,t} = 1 z_{-,t-1} = 1$
a^ϕ	$T - 1 \times D$	ecotype-varying intercept; mean value of log-odds of θ
a^π	$T - 1 \times D$	ecotype-varying intercept; mean value of log-odds of θ
m	N	species log mass, rescaled
b_1^ϕ	1	effect of species mass on log-odds of ϕ
b_1^π	1	effect of species mass on log-odds of π
b_2^ϕ	1	effect of species mass, squared, on log-odds of ϕ
b_2^π	1	effect of species mass, squared, on log-odds of π
U	$T \times D$	matrix of group-level covariates
γ^ϕ	$U \times D$	matrix of group-level regression coefficients
γ^π	$U \times D$	matrix of group-level regression coefficients
Σ^ϕ	$D \times D$	covariance matrix of a^ϕ
Σ^π	$D \times D$	covariance matrix of a^π
Ω^ϕ	$D \times D$	correlation matrix of a^ϕ
Ω^π	$D \times D$	correlation matrix of a^π
τ^ϕ	D	vector of standard deviations for each ecotype a_d^ϕ
τ^π	D	vector of standard deviations for each ecotype a_d^π

168 priors (Eq. 3).

The intercepts of ϕ and π both vary by species ecotype and those values are themselves the product
 170 of group-level regression using environmental factors as covariates (Eq. 3); this is identical to the

pure presence model (Eq. 2).

a^\phi &\sim \text{MVN}(u\gamma^\phi, \Sigma^\phi) & \Omega^\phi &\sim \text{LKJ}(2) \\
a^\pi &\sim \text{MVN}(u\gamma^\pi, \Sigma^\pi) & \Omega^\pi &\sim \text{LKJ}(2)
\end{aligned} \tag{3}$$

Posterior inference and model adequacy

Programs that implement joint posterior inference for the above models (Eqs. 2, 3) were

implemented in the probabilistic programming language Stan CITATION. The models used here both feature latent discrete parameters in the large matrix z (Tables 4, 5, 6; Eqs. 1, 2, 3). All methods for posterior inference implemented in Stan are derivative based which causes complications for actually implementing the above models because integers do not have derivatives. Instead of implementing a latent discrete parameterization, the posterior probabilities of all possible states of the latent parameters z were estimated (i.e. marginalized).

Species durations at minimum range-through from the FAD to the LAD, but the incompleteness of

all observations means that the actual time of origination or extinction is unknown. The

marginalization approach used here means that the probabilities all possible histories for a species are calculated, from the end members of the species having existed for the entire study interval and the species having only existed between the directly observed FAD and LAD to all possible intermediaries CITATION.

	Time Bin							
	1	2	3	4	5	6	7	8
Observed	0	0	0	1	0	1	1	0
Certain	?	?	?	1	1	1	1	?
Potential	0	0	0	1	1	1	1	0
Potential	0	0	1	1	1	1	1	0
Potential	0	1	1	1	1	1	1	0
Potential	1	1	1	1	1	1	1	0
Potential	0	0	0	1	1	1	1	1
Potential	0	0	1	1	1	1	1	1
Potential	0	1	1	1	1	1	1	1
Potential	1	1	1	1	1	1	1	1

Figure 2: Conceptual figure of all possible occurrence histories for an observed species.

The combined size of the dataset and large number of parameters in both models (Eqs. 2, 3), specifically the total number of latent parameters that are the matrix z , means that stochastic approximate posterior inference is computationally very slow even using HMC. Instead, an approximate Bayesian approach was used: variational inference. A recently developed automatic variational inference algorithm called “automatic differentiation variational inference” (ADVI) is implemented in Stan and was used here CITATION. ADVI assumes that the posterior is Gaussian but still yields a true Bayesian posterior; this assumption is similar to quadratic approximation of

the likelihood function used in maximum likelihood inference CITATION. The principal limitation
194 of assuming the joint posterior is Gaussian is that the true topology of the log-posterior isn't
represented; this is a particular burden for scale parameters which are bound to be positive (e.g.
196 standard deviation).

After fitting both models (Eqs. 2, 3) using ADVI, model adequacy and quality of fit was assessed
198 using a series of posterior predictive checks CITATION CITATION. Because all Bayesian models
are inherently generative, simulations of new data sets is “free” CITATION. By simulating many
200 theoretical data sets using the observed covariate information the congruence between predictions
made by the model and the observed empirical data can be assessed. By combining multiple
202 posterior predictive tests of congruence between empirical and simulated values of interest, the
holistic adequacy of the model can be analyzed CITATION.

204 An example posterior predictive check used in this study was comparing the observed average
number of observations per species to a distribution of simulated averages; if the empirically
206 observed value sits in the middle of the distribution than the model is adequate in reproducing the
observed number of occurrences per species.

208 Posterior simulations for time series are start with the values at $t = 1$ and then just simulating
forward.

Figure 4: Posterior predictive check for birth-death model.

Figure 5: Probability of ecotype occurring over time. Estimates are from the pure-presence model.

Figure 6: Probability of species origination by ecotype. Estimates are from the birth-death model.

Figure 7: Probability of species survival by ecotype. Estimates are from the birth-death model.

Figure 8: Effect of mass on probability of species preservation. Estimates are from the pure-presence model.

Figure 9: Effect of mass on probability of species preservation. Estimates are from the birth-death model.

Figure 10: Effect of mass on probability of species occurrence. Estimates are from the pure-presence model.

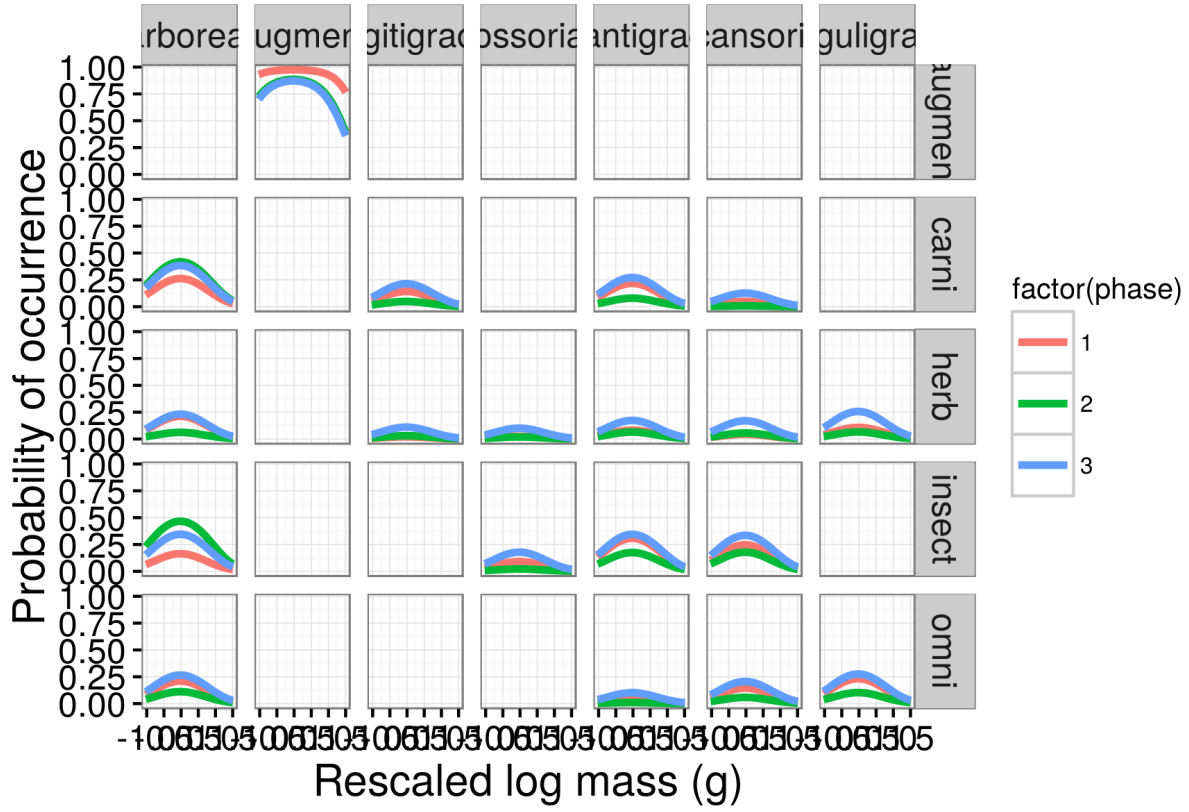

Figure 11: Effect of mass on probability of species origination. Estimates are from the birth-death model.

Figure 12: Effect of mass on probability of species survival. Estimates are from the birth-death model.

Figure 13: Effects of group-level covariates on log-odds of ecotype occurrence. Estimates are from the pure-presence model.

Figure 14: Effects of group-level covariates on log-odds of origination of species of ecotype. Estimates are from the birth-death model.

Figure 15: Effects of group-level covariates on log-odds of survival of species of ecotype. Estimates are from the birth-death model.
